Backpacking with Code: Software Portability for DHTC

Christina Koch (ckoch5@wisc.edu)
Research Computing Facilitator
University of Wisconsin - Madison
Goals for this session

• Understand the basics of...
  – how software works
  – where software is installed
  – how software is accessed and run

• ...and the implications for Distributed High Throughput Computing (DHTC)

• Describe what it means to make software “portable”

• Learn about and use two software portability techniques:
  – Build portable code
  – Use wrapper scripts
Motivation

running a piece of software is like cooking a meal in a kitchen
The Problem

Running software on your own computer = cooking in your own kitchen
The Problem

In your own kitchen:
• You have all the pots and pans you need
• You know where everything is
• You have access to all the cupboards

On your own computer:
• The software is installed, you know where it is, and you can access it.
The Problem

Running on a shared computer = cooking in someone else’s kitchen.
The Problem

In someone else’s kitchen:
- You are guaranteed some things…
- ...but others may be missing
- You don’t know where everything is
- Some of the cupboards are locked

On a shared computer:
- Your software may be missing, un-findable, or inaccessible.
The Solution

- Think like a backpacker
- Take your software with you
  - Install anywhere
  - Run anywhere
- This is called making software *portable*
Software Basics

• How do we make software portable?
• First we have to understand:
  – What software is and how it works
  – Where software lives
  – How we run it
How Software Works

• A software program can be thought of as a list of instructions or tasks that can be run on a computer.
• A launched program that is running on your computer is managed by your computer’s operating system (OS).
• The program may make requests (access this network via wireless, save to disk, use another processor) that are mediated by the OS.
• A single program may also depend on other programs besides the OS.
How Software Works*

Program (software, code, executable, binary)

Running Program (process, instance)

Operating System

Hardware (processors, memory, disk)

Program runs own tasks

Runs to makes requests

Launches to translates program’s request

Depends on monitors running programs

*Not to scale
How Software Works

Implications for DHTC:

• Software must be able to run on target operating system (usually Linux)
• Request specific OS as job requirement
• Know what else your software depends on
Location, location, location

• Where can software be installed?

```
/  
  
bin  usr  lib  programs  home
  
  bin  local

fred  wilma
```

system locations

local locations
Location, location, location

• Who can install the software?

Usually requires administrative privileges

Owner of the directory

Who can install the software?

Usually requires administrative privileges

Owner of the directory
Location, location, location

- Who can access the software?

Anyone on the system

The local user can control who has access
Implications for DHTC:

• **Software MUST be able to install to a local location**

• **Software must be installable without administrative privileges**
Command Line

Instead of graphic interface... command line

- All DHTC jobs must use software that can be run from the command line.
- The command can be used either in a script or as the job’s executable/arguments.
Location and Running Software

• To run a program on the command line, your computer needs to know where the program is located in your computer’s file system.

$ ls
$ python
$ ~/wrapper.sh

How does the command line know what `ls` is? Where is python installed?
Option 1: Use a Path

• Give the exact location of your program via a relative or absolute path:

```bash
[~$/Code]$ pwd
/Users/alice/Code

[~$/Code]$ ls
mypy/ R/ sandbox/

[~$/Code]$ mypy/bin/python --version
Python 2.7.7

[~]$ /Users/alice/Code/mypy/bin/python --version
Python 2.7.7
```
Option 2: Use “the” PATH

- The PATH is a list of locations (filesystem directories) to look for programs:

```sh
$ echo $PATH
/usr/local/bin:/usr/bin:/bin:/usr/sbin:/sbin
```

- For example, common command line programs like `ls` and `pwd` are in a system location called `bin/`, which is included in the PATH.

```sh
$ which pwd
/bin/pwd
$ which ls
/bin/ls
```
Option 2: Use “the” PATH

• You can add directories to the PATH, which allows the command line to find the command directly:

```
$ echo $PATH
/usr/local/bin:/usr/bin:/bin:/usr/sbin:/sbin

$ which python
/usr/bin/python

$ export PATH=/Users/alice/Code/mypy/bin:$PATH
$ echo $PATH
/Users/alice/Code/mypy/bin:/usr/local/bin:/usr/bin:/bin:/usr/sbin:/sbin

$ which python
/Users/alice/Code/mypy/bin/python
```
Implications for DHTC:

• Software must have ability to be run from the command line

• Multiple commands are okay, as long as they can be executed in order within a job

• There are different ways to “find” your software on the command line: relative path, absolute path, and PATH variable
Based on the previous slides, we now know that in order to make software portable for DHTC, the software:

- Must work on target operating system (probably Linux)
- Must be able to run and install without administrative privileges
- Must be accessible to your job (placed or installed in job’s working directory)
- Must be able to run from the command line, without any interactive input from you
Returning to our scenario:

In a DHTC situation, we are:

- Using someone else’s computer
  - Software may not be installed
  - The wrong version may be installed
  - We can’t find/run the installed software

Therefore:

- We need to bring along and install/run software ourselves
Portability methods

There are two primary methods to make code portable:

• Use a single compiled binary
  – Typically for code written in C, C++, and Fortran, or downloadable programs

• Use a wrapper script + “install” per job
  – Can’t be compiled into a single binary
  – Interpreted languages (e.g. Python, R)
Method 1

USE A SINGLE COMPILLED BINARY
What is Compilation?

Source code

compiled + linked

compiler and OS

libraries

Binary

uses

run on
Static Linking

Source code → compiled + static linking → Static binary

Compiler and OS → libraries → run anywhere
Compilation (command line)

```
$ ls
hello.c
$ gcc hello.c -o hello_dynamic
$ ls
hello.c hello_dynamic
$ file hello_dynamic
hello_dynamic: ELF 64-bit LSB executable, x86-64, version 1 (SYSV), dynamically linked (uses shared libs), for GNU/Linux 2.6.18, not stripped
$ gcc -static hello.c -o hello_static
$ ls
hello.c hello_dynamic hello_static
$ file hello_static
hello_static: ELF 64-bit LSB executable, x86-64, version 1 (GNU/Linux), statically linked, for GNU/Linux 2.6.18, not stripped
```
**Single Binary Workflow**

Option 1
- compile

Submit server
- Static binary

Execute server

Option 2
- download
Method 2

USE WRAPPER SCRIPTS
Set up software with every job

• Good for software that:
  – Can’t be statically compiled / compiled to one file
  – Uses interpreted languages (Matlab, Python, R)
  – Any software with instructions for local installation

• Method: write a wrapper script
  – Contains a list of commands to execute
  – Typically written in bash or simple perl/python (usually common across operating systems/versions)
Wrapper scripts

• Set up software in the working directory
  – Unpack pre-built installation OR
  – Just use normal compiled code
• Run software
• Besides software: manage data/files in the working directory
  – Move or rename output
  – Delete installation files before job completion
Wrapper script workflow

Submit server
wrapper script
source code, compiled code or pre-built install

Execute server

- set up run
- set up run
- set up run
When to pre-build?

Pre-built installation (recommended)
- Install once, use in multiple jobs
- Faster than installing from source code within the job
- Jobs must run on a computer similar to where the program was built

Install with every job (variable results)
- Computers must have appropriate tools (compilers, libraries) for software to install
- Can run on multiple systems, if these requirements are met
- Longer set-up time
Preparing your code

• Where do you compile/pre-build code? Test your wrapper script?
• Guiding question: how computationally intensive is the task?
  – Computationally intensive (takes more than a few minutes, as a rule of thumb)
    ▪ Run as interactive job, on a private computer/server, or with a queued job
  – Computationally light (runs in few minutes or less)
    ▪ Run on submit server (or above options, if desired)
Exercises

• Software is a compiled binary
  - Exercise 3.1: statically compile code and run (C code)
  - Exercise 3.2: download and run pre-compiled binary (BLAST)
Exercises

• Introduction to using wrapper scripts
  – Exercise 3.3: use a wrapper script to run previously downloaded software (BLAST)

• Portable installation and wrapper scripts
  – Exercise 3.4: create a pre-built software installation, and write a wrapper script to unpack and run software (OpenBUGS)
Exercises

• Exercise 3.5 (optional)
  – Using arguments with wrapper scripts
Questions?

• Now: Hands-on Exercises
  – 1:45-3:00pm

• Next:
  – 3:00 - 3:15pm: Break
  – 3:15 - 5:00pm: Interpreted languages
